INTRODUCTION

Rotaviruses are important etiological agents of acute viral gastroenteritis in young one of many animals’ species and human (Trojan et al., 2013; Kun et al., 2016). Rotaviruses infections cause significant economic losses in neonates of many domestic animals. Neonatal calf mortality in the first month of age is accounted to be 80 to 85% of the total mortality and is particularly high in the third week of life (Uetake, 2012; Abebaw et al., 2018).

Rotaviruses are classified in the genus Rotavirus in Reoviridae family. They are characterized by segmented genome including 11 segments of double stranded RNA contained within a triple layered protein shell composed of a core, inner capsid and outer capsid. Three structural proteins, VP1, VP2 and VP3, form the core of the Rotavirus particle (Gazal et al., 2011; Matthijnssens et al., 2011). Group A Rotaviruses are classified into G and P serotypes on the basis of outer capsids glycoprotein VP7 and VP4. Currently, 27 G-genotypes (from G1 to G27) and 35 P-genotypes (from P[1] to P[35]) have been identified in human and various species of animals in the world (Kapikian et al., 2001; Matthijnssens et al., 2012). Among these 27 G-genotypes and 35 P-genotypes, 11 G types (G1-G8, G10, G11 and G15) and 6 P-types (P[1], P[5], P[11], P[14], P[17] and P[21]) have been reported in bovine Rotavirus (RV) infection with G6, G8, G10, P[1], P[5] and P[11] predominating (Adah et al., 2003; Garaicoechea et al., 2006; Beg et al., 2010). Some studies on calves in Nigeria and Tunisia have reported the presence of G8 genotype. The work undertaken by the African Rotavirus Network...

(ARN) consortium has determined G8 and G10 in South Africa (Khuzwayo et al., 2012; Fodha et al., 2005; Esona et al., 2010). In Côte d’Ivoire, one study was conducted in 2004, and G10 genotype was detected in diarrheal calves (Akran et al., 2010).

There is no information on G and P diversity of bovine *Rotavirus* circulating locally in Abidjan district. Indeed, reduction in calf mortality rate and the economic losses of livestock in less industrialized countries is primarily based on effective vaccination. The aim of the present study was to identify genotypes circulating among bovine population of Abidjan district by using polymerase chain reaction (PCR) based typing assays.

**MATERIAL AND METHODS**

**STUDY AREA**

The study area is located in Abidjan district (south of Ivory Coast). Breeding system encountered in Ivory Coast is the extensive system. There are no specified exploitation type, we generally meet a mixed production (milk and meat). Four seasons are observed in south of Ivory Coast: two rainy seasons and two dry seasons.

**SAMPLING**

A total of 145 (135 diarrheic and 10 non-diarrheic) faecal samples were collected from bovine calves with age group up to 3 months. Samples were collected from cattle farms of different places of Abidjan district, Ivory Coast from June 2015 to May 2017. Stools were collected directly from the rectum using gloves in sterile flasks. The samples were transported in a frost containing cold accumulators and stored at -20 °C until further processing.

**VIRAL RNA EXTRACTION**

For VP4 and VP7 genes amplification, the viral RNA was extracted from collected faecal samples using QIAGEN Kit (RNA Qiamp® Viral, cat No 52906, Germany) following the manufacturer's protocol. Extracted RNA was stored at -20 °C until further use.

**PRIMERS**

Type specific primers reported for most common genotypes were selected based on available literatures. Sequences of primers, their positions in genomic segment are presented in Table 1 and 2.

**ROTAVIRUS DETECTION**

RT-PCR was performed to detect *Rotavirus* gene in the
fecal samples. Reaction was carried out by conventional method using One Step RT-PCR Kit (QIAGEN®) with pairs of forward and reverse amplification primers (VP7-F/VP7-R; VP4-F/VP4-R) to amplify respectively full-length of VP7 and VP4 gene (Iturriza-Gomara et al., 2004; Simmonds et al., 2008).

**VP7 Genotyping**

G-typing was performed using a pool of internal primers (Gouvea et al., 1994b) specific to G genotypes G5, G6, G8, G10 and G11 bovine Rotavirus genotypes in combination with an appropriate forward consensus primer (VP7-F).

The reaction was performed on a gradient thermocycler under the following conditions: reverse transcription at 50 °C for 30 minutes, followed by PCR with initial activation at 95 °C for 15 minutes, followed by 35 cycles of 94 °C for 1 minute, annealing at 48 °C for 45 seconds and extension at 72 °C for 1 minute, and a final extension of 72 °C for 10 minutes.

**VP4 Genotyping**

P-typing was performed using a pool of internal primers specific to P genotypes P[1], P[5], P[6], P[8] and P[11] bovine Rotavirus genotypes in combination with the appropriate forward consensus primer VP4-F (Gentsch et al., 1993; Gouvea et al., 1994a).

The reaction was performed on a gradient thermocycler under the same previous conditions.

**Analysis of PCR Products**

The amplified products were analyzed by electrophoresis on 1% agarose gel containing ethidium bromide for 40 minutes at 100 V. The amplicons were visualized under UV light using a UV transilluminator. Samples identified as positive were analyzed and photographed by a gel documentation system.

**RESULTS AND DISCUSSION**

All samples from non-diarrheic calves were found negative for G and P. Full length amplification of both VP4 and VP7 gene of RV was obtained with bands sizes of 663 bp and 881 bp respectively in 47/135 of all diarrheic samples (Figure 1 and 2). Overall prevalence was found to be 34.8% in diarrheic calves. This is in agreement with many epidemiological studies in herds around the world that showed that Rotavirus was present in 30-40% of fecal samples of calves with diarrhea (Fukai et al., 2002; Badaracco et al., 2012; Dhama et al., 2009).

G10 was detected in 61.7% (29/47) of positive samples with a band size of 661 bp (Figure 3). These results confirmed the previous results obtained by Akran et al. (2010). G10 was the most predominant G type in this study (Table 3). Results found in our study is in agreement with reports in México, Iran and India (Rodriguez-Limas et al., 2009; Singh and Jhala, 2011; Prasad et al., 2015; Rajendran
and Kang 2014; Nazoktabar et al., 2017); whereas in most countries such as Morocco, Hungary, Tunisia, Japan, Brazil and Europe, G6 was the most common genotype (Imane et al., 2016; Hajnalka et al., 2013, Fodha et al., 2005; Okada and Matsumoto 2002; Thabata et al. 2010; Sofie et al., 2012). G8 and G6 were not detected.

Regarding P-genotypes, the most predominant P type was P[11] which was detected in 36.1% (17/47) with a band size of 222 bp (Figure 4), followed by P[5] in 23.4% (11/47) with bands sizes of 463 bp (Figure 5). P[1], P[6] and P[8] were not detected. The present results are in accordance with those reported in many countries like Tunisia, Italy, France, Argentina, Turkey, similar to Iran, P[11] has been more frequently detected (Hassine-Zafrane et al., 2014; Sofie et al., 2012; Badaracco et al., 2012; Alkan et al., 2010; Nazoktabar et al., 2017). These results are in contrast with others studies elsewhere in the world. In these countries like Ireland (Reidy et al., 2006; Cashman et al., 2010), Brazil (Alfieri et al., 2004), and India (Gantasala et al., 2014), P[5] is more common P-type compared to P[11].

Figure 4: Agrose-gel electrophoresis of RT-PCR product of P[11] (222 bp) genotype of bovine Rotavirus. L: 100 bp plus ladder, S5, S7, S9, S12: Positive faecal samples, N: Negative Control. P: Positive Control (Bovine RV)

Figure 5: Agrose-gel electrophoresis of RT-PCR product of P[5] (463 bp) genotype of bovine Rotavirus. L: 100 bp plus ladder, S9, S22, S41, S53: Positive faecal sample. N: Negative Control. P: Positive Control (Bovine RV)

The combination G10P[11] was detected in 34% (16/47) followed by G10P[5] for 17% (8/47) of tested samples (Table 3). Similar G-P genotype combination was the most predominant combination and also recorded from different parts of the world: Tunisia (Hassine-Zafrane et al., 2014), India (Ahmed et al., 2017; Prasad et al., 2015), France and Italy (Sofie et al., 2012), Japan (Abe et al., 2009), Iran (Nazoktabar et al., 2017). No other G-P combina-
tion has been found in our study. However according to the latest reports in many countries such as Ireland (Reidy et al., 2006; Cashman et al., 2010), Australia (Swiatek et al., 2010), Argentina (Badaracco et al., 2012) and South of Africa (Khuzwayo et al., 2012); G6P[5] was the most predominant combination. Otherwise, in Brazil, Thabata et al. (2010) and Fernanda et al. (2012) found G6P[11] the most dominant in 16.2%.

In India and Ivory Coast, authors have reported the presence of animal Rotavirus G10 in human gastroenteritis (Prasad et al., 2015; Akran et al., 2010). G10P[11] genotype was found to be present in bovine population and this may be recognized as an important contributor to the diversity of RV found in human population (Prasad et al., 2015; Nazoktabar et al., 2017). This involvement of G10 Rotavirus in human gastroenteritis is a serious threat of zoonotic transmission of this virus.

Using VP7F/VP7R and VP4F/VP4R primers designed respectively by Iturriza-Gomara et al. (2001) and Simmonds et al., (2008), 80% of samples that previously untypeable using con3/con2; sBeg/Beg; End9/EndA and BovCom3/ BovCom5 (Gouvea et al.,1990; Gentsch et al.,1992; Gault et al., 1999; Isegawa et al., 1993) primers could be typed. Primers designed by Iturriza-Gomara et al. (2001) and Simmonds et al. (2008) increased the sensitivity of genotyping, comparing with others. This result is in agreement with that of Nirwati et al. (2013) in Indonesia. These authors concluded that primers designed by Iturriza-Gomara et al. (2001) and Simmonds et al. (2008), were more sensitive than those described by others.

CONCLUSION

The present study reveals that G10P[11] is predominant type of RV circulating in bovine population in Abidjan district. G10 poses a serious threat to humans because of zoonotic nature of the virus. The widespread surveillance of animal and human population is needed to determine the diversity of Rotavirus circulating in Ivory coast before adopting any immunization programs.
