**Prevalence and Molecular Detection of Intimin (eaeA) Virulence Gene in E. coli O157:H7 in Calves**

**AFAF ABDULRAHMAN YOUSIF*, MOHAMMED ALI HUSSEIN**

Department of Internal and Preventive Veterinary Medicine, College of Veterinary Medicine, University of Baghdad, Iraq.

**Abstract** | This study was carried out to investigate the prevalence of *Escherichia coli* O157:H7 serotype from diarrheic and non-diarrheic calves. The study was out in Baghdad, a province in Iraq. A total of 350 faecal samples from 35 diarrheic calves and 315 non-diarrheic calves with different ages (up to 1 year) and from both sexes. After initially enrichment, samples were streaked on sorbitol MacConkey agar plus cefixime potassium tellurite (SMA-CT) and Chrom agar™ *E. coli* O157:H7. Non-sorbitol fermenting (NSF) *E. coli* isolates were conducted to serotyping using commercial Latex agglutination test for detection of O157 and H7 antigen. *E. coli* isolates were additionally tested for virulence factor eae by PCR techniques. Four isolates (11.42%) belonged to *E. coli* O157:H7 in 35 diarrheic calves and 28 (8.88%) in non-diarrheic calves. All four isolates from diarrheic calves were found positive for intimin (eaeA) gene (100%) and only 13 from 28 isolates (46.42%) were possessing (eaeA) gene in non-diarrheic calves. In conclusion, this study revealed the importance of calves to act as a reservoir for *E. coli* O157:H7. Also, the eaeA genes in a high percentage in most calves suggest that they may be virulent for humans.

**INTRODUCTION**

**Enterohemorrhagic Escherichia coli** (EHEC) strains, of which *E. coli* O157:H7 is the best-studied serotype, Shiga toxin-producing *Escherichia coli* O157:H7 causes foodborne infections, and cattle are the primary reservoir which harbour the bacteria in their intestinal tracts without showing clinical symptoms (Kieckens et al., 2015; Katani et al., 2015).

Enterohemorrhagic *Escherichia coli* (EHEC) O157:H7 responsible for frequent haemorrhagic colitis and haemolytic uremic syndrome in humans. In 1982 *E. coli* O157:H7 was first recognized as a human pathogen (Riley et al., 1982). As it was associated with consumption of undercooked ‘hamburgers’. As it has been found that healthy cattle can harbour the bacteria, ruminants are now regarded as its main reservoir, though STEC O157:H7 has been isolated from other animal species such as pigs, sheep, geese, gulls, geese and pet animals (Gyles, 2007).

The ability of the organism to survive in feed, water, soil and manure has important implications for its persistence in cattle herds and contamination of water supplies and crops. Effective measures to reduce or eliminate *E. coli* O157:H7 in cattle will reduce not only foodborne illness but also the risk of transmission of the organism into the environment (Bach et al., 2002).

A wide range of prevalence estimates ranging from 0.1% to 62% of *E. coli* O157 in cattle was reported worldwide (Lin et al., 2001; Reinstein et al., 2009; Pennington, 2010). The inconsistent prevalence estimates of *E. coli* O157 reported in cattle in various geographical locations might be, to some extent, due to variable methodological modus operandi to identify the organism, such as sampling strategy, type of samples, enrichment procedures, immunomagnetic separation and cultural media of choice. Therefore, the fac-
tors that contribute to the variability in the detection of the organism and thus in the prevalence estimate need to be identified by analysing the available published reports (Islam et al., 2014).

The “top five” EHEC serotypes are defined as *E. coli* strains harbouring Shiga toxin (*stx*) and intimin (*eae*) genes and belonging to one of the following serotypes: O157:H7, O26:H11, O103:H2, O111:H8, and O145:H28 (ANS-ES, 2010). Intimin (*eaeA* gene) and Tir (*tir* gene) are key colonization factors, which play significant roles in *E. coli* O157:H7 attachment to host epithelium (McNeilly et al., 2010; Zhang et al., 2014).

Blanco et al. (2004) recorded that Intimin is required for intimate bacterial adhesion to epithelial cells inducing a characteristic histopathological lesion defined as “attaching and effacing” (A/E). This lesion is governed by a large pathogenicity island named the locus of enterocyte effacement (LEE). The products of LEE are a type III secretion system, intimin and its translocated intimin receptor, and other secreted proteins. The secretion system is a molecular syringe for which secreted proteins are transferred into host cell cytoplasm. Intimin is encoded by *eae* gene that presents heterogeneity in their 3’ end, involved in binding to the enterocytes.

This study was the first in Iraq aimed to isolate and confirm *E. coli* O157:H7 serotypes in the faecal samples of calves located place around Baghdad province and to determine the *eaeA* virulence genes in these strains by PCR technique.

**MATERIALS AND METHODS**

**Bacteriological Examination**

Three hundred fifty calves aged between (up to one year), from both sexes found in field at different places in Baghdad city, for six months (November 2014 to April 2015). All methods of culturing, Gram stain and biochemical tests were done according to (Marky et al., 2014). Samples were cultured on MacConkey agar and Eosin Methylene blue agar and incubated aerobically at 37°C for 24-48 hours; the growing colonies were examined by naked eye concerning their shape, size and color. Then bacterial cells were stained by gram stain. IMViC” tests (Indole, Methyl Red, Voges-Proskauer and Citrate) and Triple sugar iron medium. Culturing on two specific media, Cefixime Tellurite - Sorbitol MacConkey agar (CT-SMAC) [LABM™ (England) ] and CHROM agar O157 [The Pioneer of Chromogenic Media/Paris] according to (Chow et al., 2006) and confirmation by using Latex agglutination Test for *E. coli* O157:H7. This test was used for serotyping of *E. coli* O157:H7 by using commercial kit (Wellcolex *E. coli* O157:H7, Remel) to detect both the somatic antigen O157 and the flagellar antigen H7 according to the manufacturer company.

**PCR ASSAY FOR DETECTION OF eaeA GENE IN ISOLATED E. COLI O157:H7.**

**DNA extraction:** Genomic DNA of *E. coli* O157:H7 isolate was extracted by using (Presto™ Mini g DNA Bacteria Kit Geneaid. USA) according to manufacture procedure.

**Oligonucleotide primer:** The oligonucleotide primers for *eaeA* gene were:

- F -5’ GAC CCG GCA CAA GCA TAA GC -3’
- R -5’ CCA CCT GCA GCA ACA AGA GG -3’

The product size was 384 pb were designed by (Paton and Paton, 1998). The purity and concentration of extracted DNA was measured using Nanodrop spectrophotometer (NuDrops)™ [ActGene(USA)] .

**Gel electrophoresis for check extracted DNA:** It was very important step to complete PCR assay, which was used to check the extracted DNA by loading the eluted DNA by agarose gel electrophoresis.

**Preparation of PCR Master Mix:** All required reagents were thawed completely and put them on ice, and reagent was mixed well by inversion and spins them down prior to pipetting. PCR master mix reaction was prepared by using GoTaq® Green Master Mix from Promega, USA.

The PCR tubes containing an amplification mixture were transferred to thermal-cycler and started the program for amplification as shown in the Table 1.

**PCR Product Analysis (Agarose Gel Electrophoresis):**

It is a very important step to complete PCR assay, which was used to analyse the PCR product by agarose gel electrophoresis. Finally PCR products (bands) were visualized using a UV transilluminator[ Cleaver Scientific (U.K.)] and photographed by using digital camera.

RESULTS

**E. coli O157:H7 Isolation**

Different morphological shape and colour of *E. coli* colonies were appeared on different media. The colonies revealed red/pink colour on MacConkey agar and metallic sheen on Eosin Methylene Blue. The Gram stain of suspected *E. coli* colonies revealed, negative non spore forming rod. The isolated bacteria gave different reaction in biochemical tests. It gave negative for Voges–proskauer, simmon citrate and positive for indole and motility tests. The Triple sugar Iron test (TSI) showed Yellow with/without gas production. The isolated colonies of *E. coli* appeared small, circular and colourless with smoky centre (1–2) mm in diameter on SMA-CT. On Chrome agar the colonies of *E. coli* O157 showed mauve colour.

**Serotyping Test (Wellcolex E. coli O157:H7, Remel)**

*Escherichia coli* colonies from (SMA-CT) were tested for identification of both O157:H7 antigens by Wellcolex *E. coli* O157:H7, Remel. The isolates that gave a positive reaction for the O157 antigen were sub-cultured overnight on blood agar for the detection of flagellar antigen (H7). Red colour agglutination indicated a positive result for (O antigen) in comparison to clear red colour of the control and the blue colour agglutination indicated positive result for (H antigen) in comparison to clear blue colour of the control.

**Prevalence of E. coli O157:H7 in Calves**

*E. coli* was isolated at a high percentage from samples of diarrheic and non-diarrheic calves, *E. coli* O157:H7 appeared in 4 isolates (11.42%) from diarrheic calves, and 28 isolates of *E. coli* O157:H7 were isolated from non-diarrheic calves (Table 2).

**E. coli O157:H7 Confirmation by PCR**

The confirmation process of the *E. coli* O157:H7 isolates recovered from fecal samples of calves to detect the presence of specific virulence trait eaeA gene by PCR assay, all four isolates from diarrheic calves were possess eaeA gene (100%) and 13 (46.42%) of isolates from non-diarrheic calves were positive for eaeA gene. The study revealed that 17(53.12%) from total isolates gave positive results with eaeA primers equal to target product size(384bp) (Table 3 and Figure 1).

**Discussion**

This is the first study which describes the detection and frequency of major virulence genes of STEC isolated from cattle in Baghdad, Iraq. Study revealed 4 isolates of *E. coli* O157:H7 from 35 fecal samples at a percent (11.42%) in diarrheic calves and all these isolates possessed eaeA gene. Non diarrheic calves showed 28(8.88%) positive samples and 13(46.42%) possessed eaeA gene.

*Escherichia coli* O157:H7 are generally recognized by culturing on different media, on sorbitol MacConkey agar supplemented with cefixime and potassium tellurite (CT-SMAC), these results were compatible with Garcia et al. (2010) were they found that typical *E. coli* O157:H7 appeared as colourless colonies and do not fermented sorbitol on SMAC agar while most non-O157 strains ferment sorbitol and appear as pink colour colonies on SMAC agar.

Another group of researcher, Tahamtan et al. (2011) use sorbitol-MacConkey agar plate supplemented with potassium tellurite (2.5 mg/L) and variant cefixime (0.05 mg/L). The *E. coli* O157:H7 on SMAC agar Non diarrheic calves showed 28(8.88%) positive samples and 13(46.42%) possessed eaeA gene.
Our results showed that Chrome agar aids in diagnosis of *E. coli* O157:H7, it utilizes one of chromogenic substrates which produce mauve colour colonies, while non- *E. coli* O157:H7 organism may utilize chromogenic substrates resulting in blue to blue green colour colonies, our results are in agreement with Tavakoli et al. (2008) who recorded that the use of chrome agar allowed presumptive identification of *E. coli* O157:H7 from the primary isolation plate and differentiation from other organisms. A similar study by Yousif and Al-Taii (2014) reported that the Chrom agar is useful for diagnosis of *Escherichia coli* O157:H7.

Latex agglutination test appeared a highly sensitive and specific for the diagnosis of *E. coli* O157:H7, this results in agreement with Yousif and Al-Taii (2014), Al-Dawmy and Yousif (2013) and Karmali et al. (1999) who used latex agglutination test for serotyping of *E. coli* O157:H7. And describe it as a rapid, reliable, easy to perform and interpret, and it should allow testing for VT to become more widely performed.

The percentage of *E. coli* O157 isolation from calves were compatible with Omisakin et al. (2003) they reported the prevalence of carriage of *E. coli* O157 in faeces of cattle was 7.5% and with study of Alam and Zurek (2006) who found the prevalence of *Escherichia coli* O157:H7 in beef cattle faeces was (9.2%) Another study conducted by Kang et al. (2004) was compatible with our study as they found the prevalence of *E. coli* O157 in diarrheic calves at percentage 9.8% and with Kuyucuoglu et al. (2011) as they estimate the prevalence of *E. coli* O157:H7 in diarrheic calves at percentage (10.6). Whereas Blanco et al. (1993) found that the prevalence of *Eschrechia coli* O157:H7 in the faeces of dairy calves and feedlot cattle is low (0.3 to 2.2%) in the United States, the United Kingdom, Germany, and Spain. While Mechie et al. (1997) recorded the prevalence of *Escherichia coli* O157:H7 in calves a high percentage (56%) in England.

The prevalence of *E. coli* O157:H7 in the current study was higher than that reported by El-Shehedi et al. (2013) in AL-Qalyoubi Governorate in Egypt in diarrhoeic calves at level 6.97%.

In non-diarrheic calves, the results showed that the prevalence of *E. coli* O157:H7 (8.88%) was higher than the percentage recorded by Kuyucuoglu et al. (2011), as they found 2.6% of healthy calves infected with *E. coli* O157:H7.

The occurrence of *E. coli* O157:H7 were also detected in different regions of Turkey. For instances, *E. coli* O157 was found in 14 individuals among 330 cattle slaughtered in five different abattoir in Istanbul (Yilmaz et al., 2002) and *E. coli* O157:H7 were isolated in 4 individuals among 312 cattle in the eastern region of Turkey (Aslantas et al., 2006). In another study, the rate of *E. coli* O157:H7 infection was found to be 13.6% (Cabalar et al., 2001), this point was very important because turkey was a neighbouring country to Iraq.

The results showed that *eaeA* gene found in a percentage (53.12%) in isolates of *E. coli* O157:H7 from diarrheic and non-diarrheic calves. This results agreed with Galland et al. (2001) who found that 26 from 57 *Escherichia coli* O157:H7 beef cattle feedlots in southwest Kansas were *eaeA* gene positive. But other researcher record a high percentage (100%), Schouten et al. (2004) found all *Escherichia coli* O157 isolates on Dutch dairy farms show positive for *eaeA* gene, Synge et al. (2003) recorded that all of the VTEC O157 tested were *eaeA* positive from beef suckler cows in Scotland and Alam and Zurek (2006) showed that all tested isolates of *Escherichia coli* O157:H7 in beef cattle were positive for *eaeA* (Intimin) gene.

Gene *eaeA* (Intimin) which was a necessary gene for attaching and effacing activity (Kaper et al., 1998). Many investigators have underlined the strong association between carrying *eaeA* and the capacity of STEC to cause severe human disease, especially HUS (Oswald et al., 2000). In the present study, this important virulence gene was detected in 100% of STEC O157:H7 in diarrheic calves and (46.42%) of non-diarrheic calves isolates. A similar prevalence of the intimin (*eaeA*) gene has also been found in other studies (Blanco et al., 2001; Blanco et al., 2004).

Epidemiological studies on EHEC in cattle are very necessary to develop control measures in order to reduce the risk of transmission from cattle to humans. Since isolation procedures are laborious and time-consuming and because of the lack of biochemical features distinguishing most EHEC strains from nonpathogenic *E. coli*, PCR approaches based on the detection of EHEC-associated genetic markers have been developed (Bibbal et al., 2014).

In conclusion, this study revealed the importance of *E. coli* O157:H7 serotype calves, which represent as a reservoir for strains that transmitted the disease to human. *E. coli* O157:H7 virulence gene *eaeA* ( intimin) was detected in faeces samples collected from calves using PCR. Therefore, we believe that the isolation of *E. coli* O157:H7 serotypes in Iraq will be beneficial to the many researchers in this field and for investigation of future epidemiological study.
